

# high profile supply chain attack

By [GReAT](#), [AMR](#) on April 23, 2019. 10:00 am

In late March 2019, we [briefly highlighted](#) our research on ShadowHammer attacks, a sophisticated supply chain attack involving ASUS Live Update Utility, which was [featured](#) in a Kim Zetter article on Motherboard. The topic was also one of the research announcements made at [the SAS conference](#), which took place in Singapore on April 9-10, 2019. Now it is time to share more details about the research with our readers.

At the end of January 2019, Kaspersky Lab researchers discovered what appeared to be a new attack on a large manufacturer in Asia. Our researchers named it "Operation ShadowHammer".

Some of the executable files, which were downloaded from the official domain of a reputable and trusted large manufacturer, contained apparent malware features. Careful analysis confirmed that the binary had been tampered with by malicious attackers.

It is important to note that any, even tiny, tampering with executables in such a case normally breaks the digital signature. However, in this case, the digital signature was intact: valid and verifiable. We quickly realized that we were dealing with a case of a compromised digital signature.

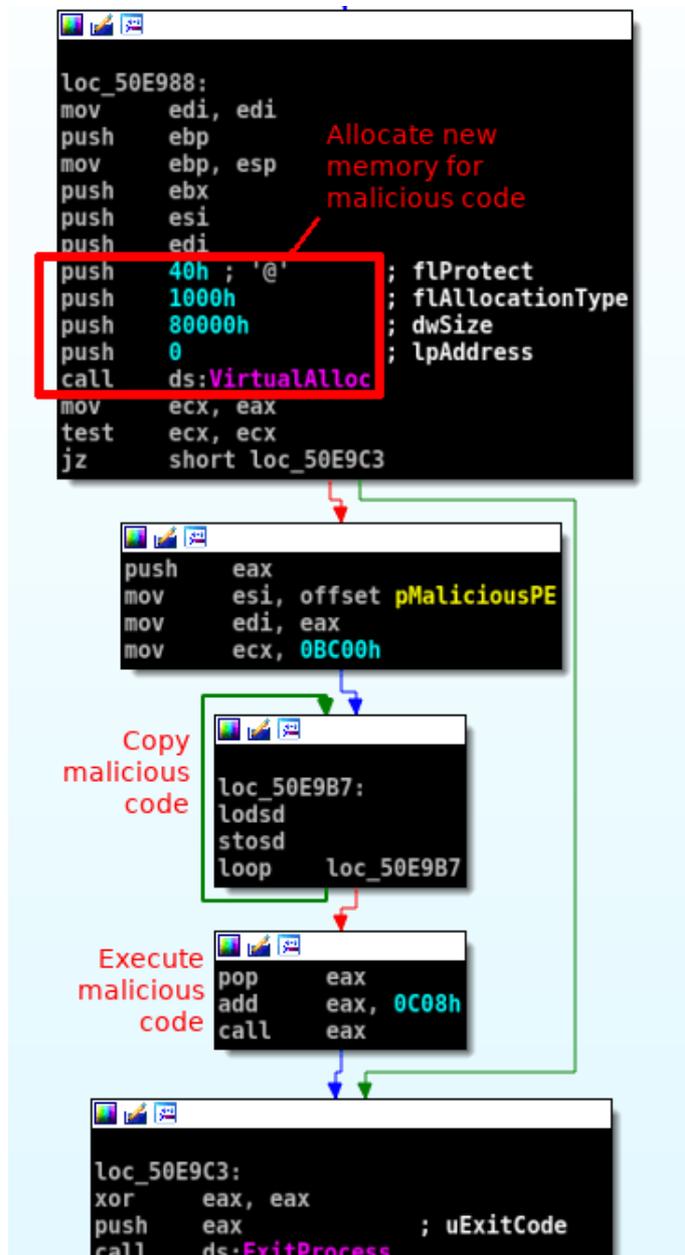

We believe this to be the result of a sophisticated supply chain attack, which matches or even surpasses the [ShadowPad](#) and the [CCleaner](#) incidents in complexity and techniques. The reason that it stayed undetected for so long is partly the fact that the trojanized software was signed with legitimate certificates (e.g. "ASUSTeK Computer Inc.").

The goal of the attack was to surgically target an unknown pool of users, who were identified by their network adapters' MAC addresses. To achieve this, the attackers had hardcoded a list of MAC addresses into the trojanized samples and the list was used to identify the intended targets of this massive operation. We were able to extract more than 600 unique MAC addresses from more than 200 samples used in the attack. There might be other samples out there with different MAC addresses on their lists, though.

# Technical details

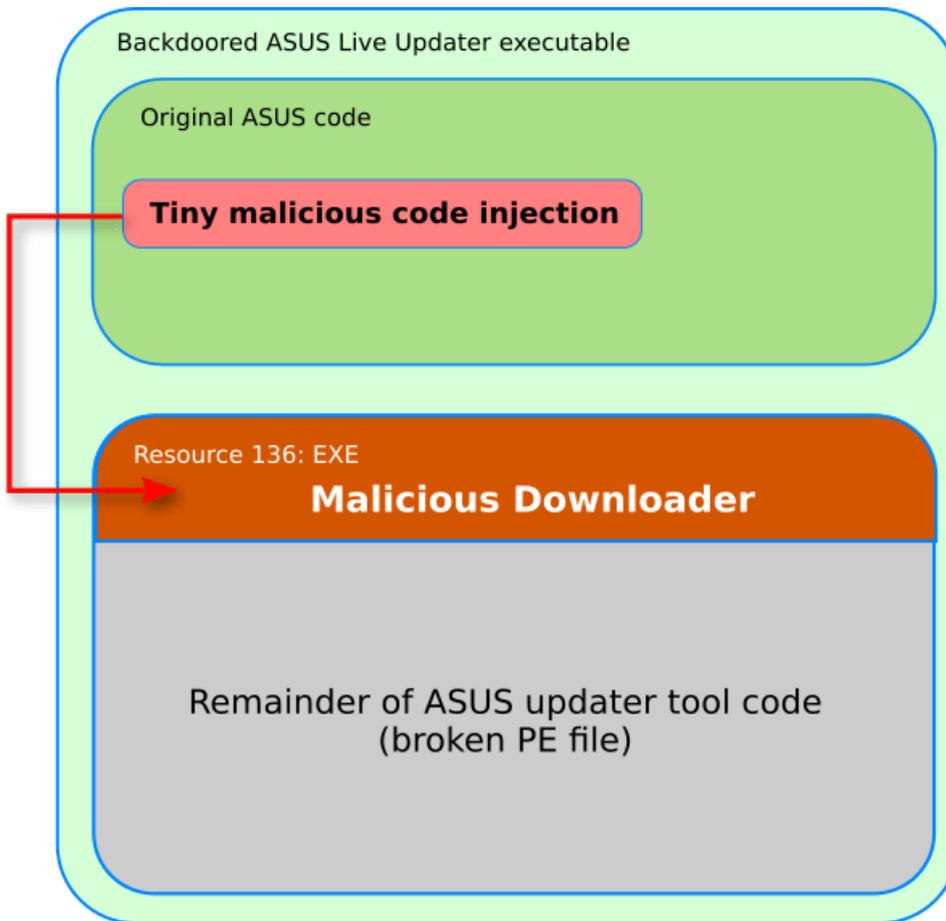

The research started upon the discovery of a trojanized ASUS Live Updater file (setup.exe), which contained a digital signature of ASUSTeK Computer Inc. and had been backdoored using one of the two techniques explained below.

In earlier variants of ASUS Live Updater (i.e. MD5:0f49621b06f2cdaac8850c6e9581a594), the attackers replaced the WinMain function in the binary with their own. This function copies a backdoor executable from the resource section using a hardcoded size and offset to the resource. Once copied to the heap memory, another hardcoded offset, specific to the executable, is used to start the backdoor. The offset points to a position-independent shellcode-style function that unwraps and runs the malicious code further.

Some of the older samples revealed the project path via a PDB file reference: "D:\C++\AsusShellCode\Release\AsusShellCode.pdb". This suggests that the attackers had exclusively prepared the malicious payload for their target. A similar tactic of precise targeting has become a persistent property of these attackers.

A look at the resource section used for carrying the malicious payload revealed that the attackers had decided not to change the file size of the ASUS Live Updater binary. They changed the resource contents and overwrote a tiny block of the code in the subject executable. The layout of that patched file is shown below.

We managed to find the original ASUS Live Updater executable which had been patched and abused by the attackers. As a result, we were able to recover the overwritten data in the resource section. The file we found was digitally signed and certainly had no infection present.

Both the legitimate ASUS executable and the resource-embedded updater binary contain timestamps from March 2015. Considering that the operation took place in 2018, this raises the following question: why did the attackers choose an old ASUS binary as the infection carrier?

Another injection technique was found in more recent samples. Using that technique, the attackers patched the code inside the C runtime (CRT) library function "\_\_\_crtExitProcess". The malicious code executes a shellcode loader instead of the standard function "\_\_\_crtCorExitProcess":

```

; Attributes: library function noreturn bp-based frame
; void cdecl __noreturn ___crtExitProcess(UINT uExitCode)
___crtExitProcess proc near
    uExitCode= dword ptr 8
    mov     edi, edi
    push   ebp
    mov   ebp, esp
    push   [ebp+uExitCode]
    call  execute_shellcode
    pop   ecx
    push   [ebp+uExitCode] ; uExitCode
    call  ds:ExitProcess
    ___crtExitProcess endp
  
```

```

; Attributes: library function noreturn bp-based frame
; void cdecl __noreturn ___crtExitProcess(UINT uExitCode)
___crtExitProcess proc near
    uExitCode= dword ptr 8
    mov     edi, edi
    push   ebp
    mov   ebp, esp
    push   [ebp+uExitCode]
    call  ___crtCorExitProcess
    pop   ecx
    push   [ebp+uExitCode] ; uExitCode
    call  ds:ExitProcess
    ___crtExitProcess endp
  
```

This way, the execution flow is passed to another address which is located at the end of the code section. The attackers used a small decryption routine that can fit into a block at the end of the code section, which has a series of zero bytes in the original executable. They used the same source executable file from ASUS (compiled in March 2015) for this new type of injection.

```
1 int __stdcall decryptShellcode(BYTE *input, int size, BYTE *output)
2 {
3     int result; // eax
4     unsigned int d; // [esp+00h] [ebp-44h]
5     unsigned int c; // [esp+0Ch] [ebp-38h]
6     unsigned int b; // [esp+E8h] [ebp-2Ch]
7     unsigned int a; // [esp+F4h] [ebp-20h]
8     int i; // [esp+10Ch] [ebp-8h]
9
10    i = 0;
11    a = *(_DWORD *)input;
12    b = *(_DWORD *)input;
13    c = *(_DWORD *)input;
14    d = *(_DWORD *)input;
15    do
16    {
17        a = a + (a >> 3) - 0x11111111;
18        b = b + (b >> 5) - 0x22222222;
19        c += 0x33333333 - (c << 7);
20        d += 0x44444444 - (d << 9);
21        output[i] = (d + c + b + a) ^ input[i];
22        result = ++i;
23    }
24    while ( i < size );
25    return result;
26 }
```

We believe that the attackers changed the payload start routine in an attempt to evade detection. Apparently, they switched to a better method of hiding their embedded shellcode at some point between the end of July and September 2018.

## ShadowHammer downloader

The compromised ASUS binaries carried a payload that was a Trojan downloader. Let us take a closer look at one such ShadowHammer downloader extracted from a copy of the ASUS Live Updater tool with MD5:0f49621b06f2cdaac8850c6e9581a594. It has the following properties:

MD5: 63f2fe96de336b6097806b22b5ab941a

SHA1: 6f8f43b6643fc36bae2e15025d533a1d53291b8a

SHA256:

1bb53937fa4cba70f61dc53f85e4e25551bc811bf9821fc47d25de1be9fd  
286a

Digital certificate fingerprint:

0f:f0:67:d8:01:f7:da:ee:ae:84:2e:9f:e5:f6:10:ea

File Size: 1'662'464 bytes

File Type: PE32 executable (GUI) Intel 80386, for MS Windows

Link Time: 2018.07.10 05:58:19 (GMT)

The relatively large file size is explained by the presence of partial data from the original ASUS Live Updater application appended to the end of the executable. The attackers took the original Live Updater and overwrote it with their own PE executable starting from the PE header, so that the file contains the actual PE image, whose size is only 40448 bytes, while the rest comes from ASUS. The malicious executable was created using Microsoft Visual C++ 2010.

The core function of this executable is in a subroutine which is called from WinMain, but also executed directly via a hardcoded offset from the code injected into ASUS Live Updater.

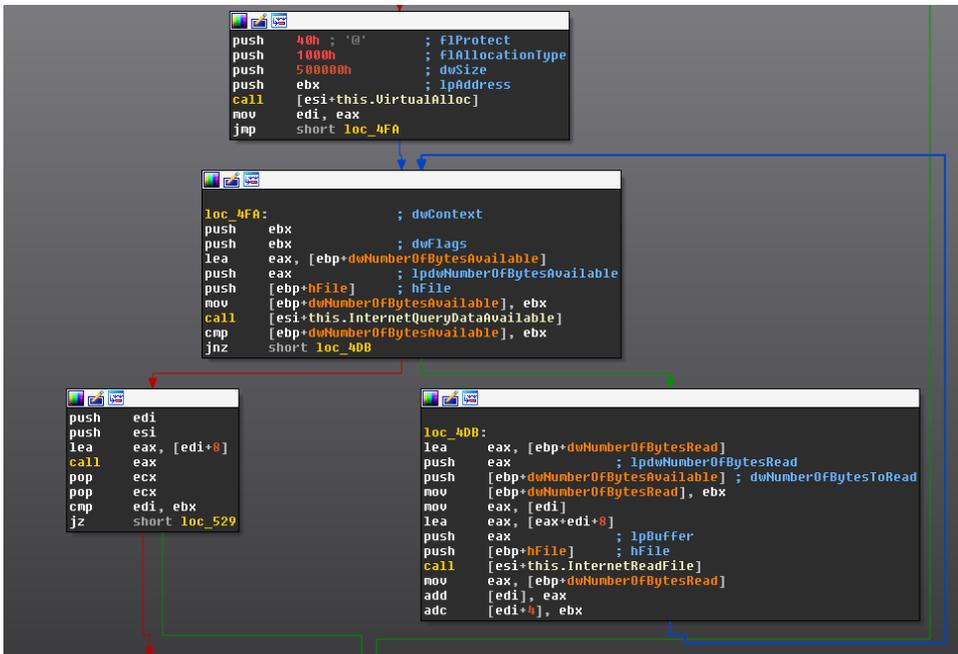

The code uses dynamic import resolution with its own simple hashing algorithm. Once the imports are resolved, it collects MAC addresses of all available network adapters and calculates an MD5 hash for each of these. After that, the hashes are compared against a table of 55 hardcoded values. Other variants of the downloader contained a different table of hashes, and in some cases, the hashes were arranged in pairs.

```
xor    eax, eax
mov    [esp+0DC0h+var_494], ecx
mov    [esp+0DC0h+var_490], 0F39DDA09h

mov    [esp+0DC0h+var_45C], ██████████
mov    [esp+0DC0h+var_458], ██████████
lea   edi, [esp+0DC0h+var_454]
stosd
```

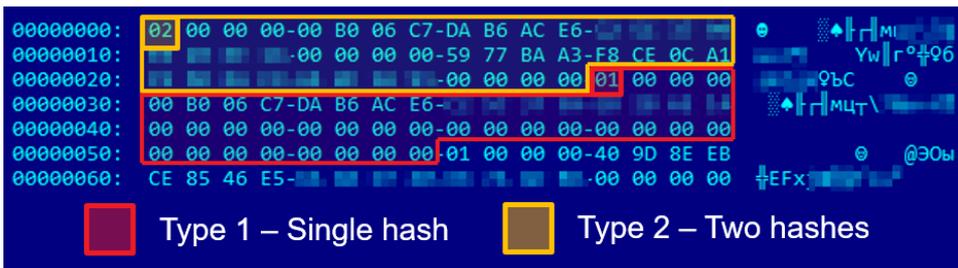

Hardcoded MD5 values

In other words, the malware iterates through a table of hashes and compares them to the hashes of local adapters' MAC hashes. This way, the target system is recognized and the malware proceeds to the next stage, downloading a binary object from [https://asushotfix\[.\]com/logo.jpg](https://asushotfix[.]com/logo.jpg) (or [https://asushotfix\[.\]com/logo2.jpg](https://asushotfix[.]com/logo2.jpg) in newer samples). The malware also sends the first hash from the match entry as a parameter in the request to identify the victim. The server response is expected to be an executable shellcode, which is placed in newly allocated memory and started.

Our investigation uncovered 230 unique samples with different shellcodes and different sets of MAC address hashes. This leads us to believe that the campaign targeted a vast number of people or companies. In total, we were able to extract 14 unique hash tables. The smallest hash table found contained eight entries and the biggest, 307 entries. Interestingly, although the subset of hash entries was changing, some of the entries were present in all of the tables.

For all users whose MAC did not match expected values, the code would create an INI file located two directory levels above the current executable and named "idx.ini". Three values were written into the INI file under the [IDX\_FILE] section:

```

[IDX_FILE]
XXX_IDN=YYYY-MM-DD
XXX_IDE=YYYY-MM-DD
XXX_IDX=YYYY-MM-DD
    
```

where YYYY-MM-DD is a date one week ahead of the current system date.

The code injected by the attackers was discovered with over 57000 Kaspersky Lab users. It would run but remain silent on systems that were not primary targets, making it almost impossible to discover the

anomalous behavior of the trojanized executables. The exact total of the affected users around the world remains unknown.

# Digital signature abuse

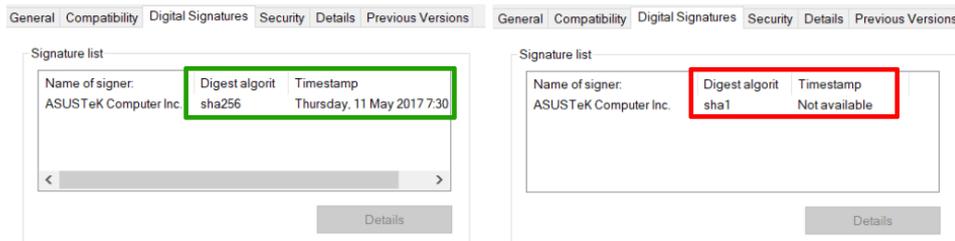

A lot of computer security software deployed today relies on integrity control of trusted executables. Digital signature verification is one such method. In this attack, the attackers managed to get their code signed with a certificate of a big vendor. How was that possible? We do not have definitive answers, but let us take a look at what we observed.

First of all, we noticed that all backdoored ASUS binaries were signed with two different certificates. Here are their fingerprints:

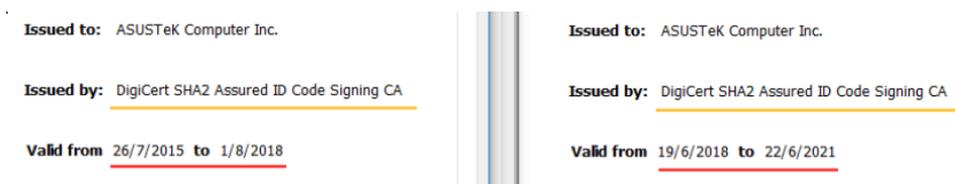

- 0ff067d801f7daeeae842e9fe5f610ea
- 05e6a0be5ac359c7ff11f4b467ab20fc

The same two certificates have been used in the past to sign at least 3000 legitimate ASUS files (i.e. [ASUS GPU Tweak](#), [ASUS PC Link](#) and others), which makes it very hard to revoke these certificates.

All of the signed binaries share certain interesting features: none of them had a signing timestamp set, and the digest algorithm used was SHA1. The reason for this could be an attempt at hiding the time of the operation to make it harder to discover related forensic artefacts.

Although there is no timestamp that can be relied on to understand when the attack started, there is a mandatory field in the certificate, "Certificate Validity Period", which can help us to understand roughly the timeframe of the operation. Apparently, because the certificate that the attackers relied on expired in 2018 and therefore had to be reissued, they used two different certificates.

Another notable fact is that both abused certificates are from the DigiCert SHA2 Assured ID Code Signing CA.

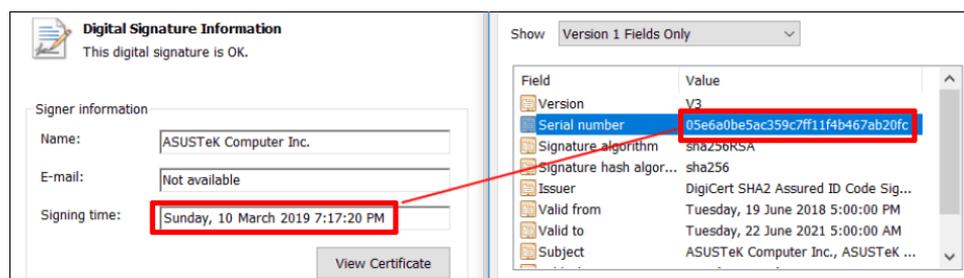

**Issued to:** ASUSTeK Computer Inc.

**Issued by:** DigiCert EV Code Signing CA (SHA2)

**Valid from** 15/6/2015 **to** 19/6/2018

The legitimate ASUS binaries that we have observed use a different certificate, which was issued by the DigiCert EV Code Signing CA (SHA2). EV stands for “[Extended Validation](#)” and provides for stricter requirements for the party that intends to use the certificate, including hardware requirements. We believe that the attackers simply did not have access to a production signing device with an EV certificate.

This indicates that the attackers most likely obtained a copy of the certificates or abused a system on the ASUS network that had the certificates installed. We do not know about all software with malware injection they managed to sign, and we believe that the compromised signing certificates must be removed and revoked. Unfortunately, one month after this was reported to ASUS, newly released software (i.e. md5: 1b8d2459d4441b8f4a691aec18d08751) was still being signed with a compromised certificate. We have immediately notified ASUS about this and provided evidence as required.

## ASUS-related attack samples

Using decrypted shellcode and through code similarity, we found a number of related samples which appear to have been part of a parallel attack wave. These files have the following properties:

- they contain the same shellcode style as the payload from the compromised ASUS Live Updater binaries, albeit unencrypted
- they have a forgotten PDB path of “D:\C++\AsusShellCode\Release\AsusShellCode.pdb”
- the shellcode from all of these samples connects to the same C2: asushotfix[.]com
- all samples were compiled between June and July 2018
- the samples have been detected on computers all around the globe

The hashes of these related samples include:

```
322cb39bc049aa69136925137906d855
36dd195269979e01a29e37c488928497
7d9d29c1c03461608bcab930fef2f568
807d86da63f0db1fc746d1f0b05bc357
849a2b0dc80aeca3d175c139efe5221c
86A4CAC227078B9C95C560C8F0370BF0
98908ce6f80ecc48628c8d2bf5b2a50c
a4b42c2c95d1f2ff12171a01c86cd64f
b4abe604916c04fe3dd8b9cb3d501d3f
eac3e3ece94bc84e922ec077efb15edd
128CECC59C91C0D0574BC1075FE7CB40
88777aacd5f16599547926a4c9202862
```

These files are dropped by larger setup files / installers, signed by an ASUS certificate (serial number: 0ff067d801f7daeeae842e9fe5f610ea) valid from 2015-07-27 till 2018-08-01).

The hashes of the larger installers/droppers include:

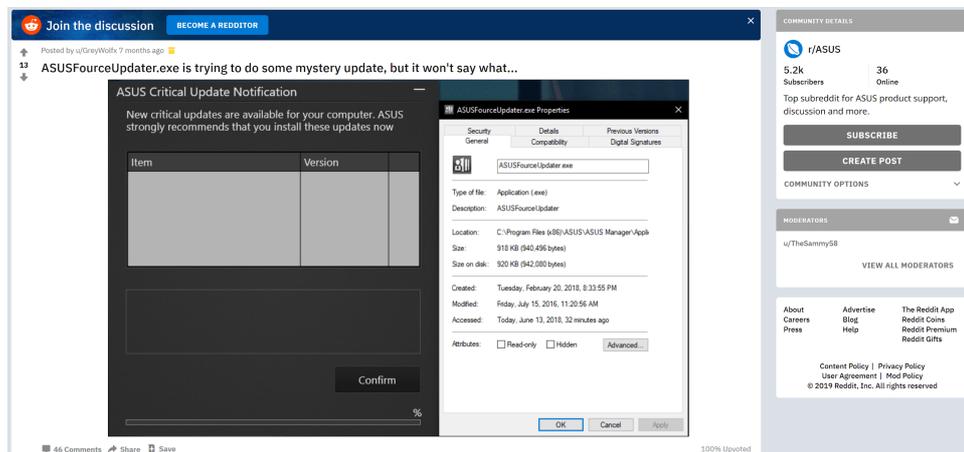

```
0f49621b06f2cdaac8850c6e9581a594
17a36ac3e31f3a18936552aff2c80249
```

At this point, we do not know how they were used in these attacks and whether they were delivered via a different mechanism. These files were located in a "TEMP" subfolder for ASUS Live Updater, so it is possible that the software downloaded these files directly. Locations where these files were detected include:

- asus\asus live update\temp\1\Setup.exe
- asus\asus live update\temp\2\Setup.exe
- asus\asus live update\temp\3\Setup.exe
- asus\asus live update\temp\5\Setup.exe
- asus\asus live update\temp\6\Setup.exe
- asus\asus live update\temp\9\Setup.exe

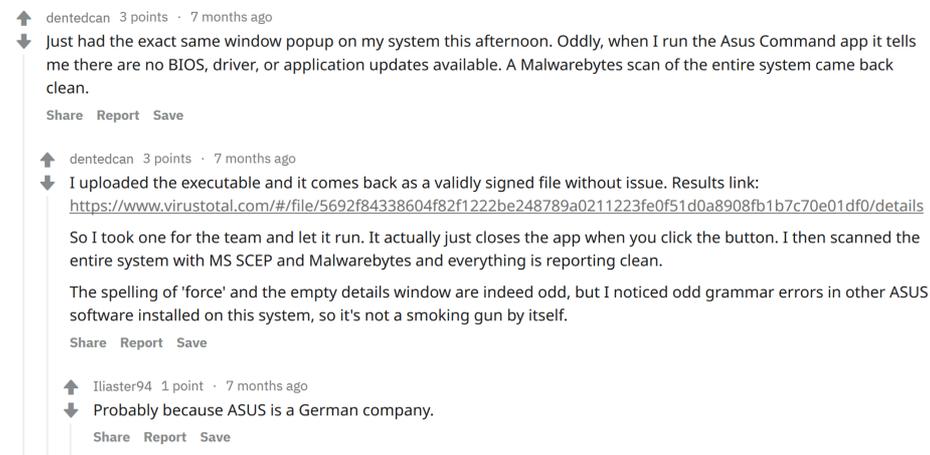

## Public reports of the attack

While investigating this case, we were wondering how such a massive attack could go unnoticed on the Internet. Searching for any kind of evidence related to the attack, we came by a Reddit thread created in June 2018, where user GreyWolfx posted a screenshot of a suspicious-looking ASUS Live Update message:

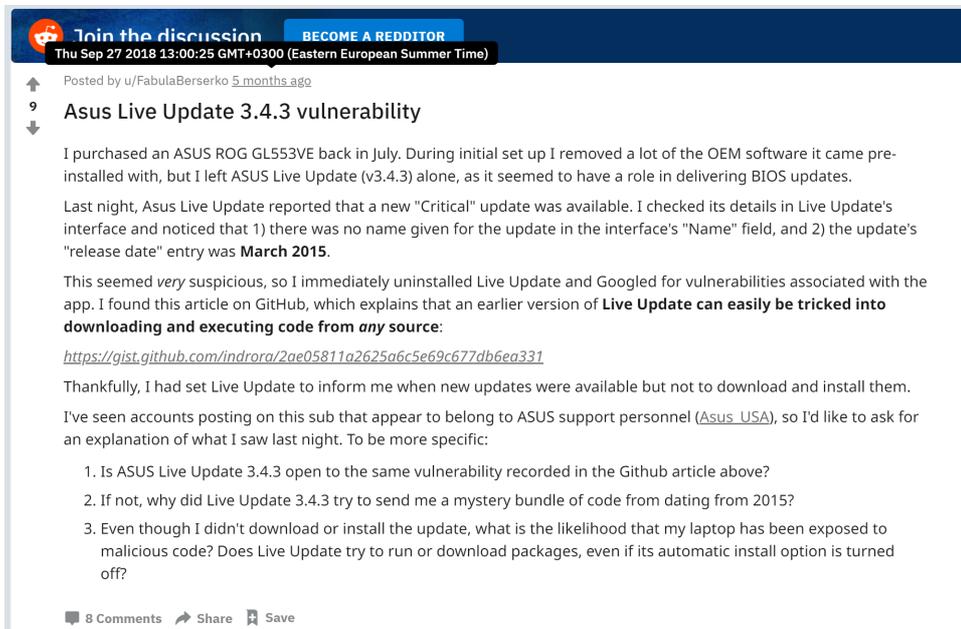

The message claims to be a "ASUS Critical Update" notification, however, the item does not have a name or version number.

Other users commented in the thread, while some uploaded the suspicious updater to VirusTotal:

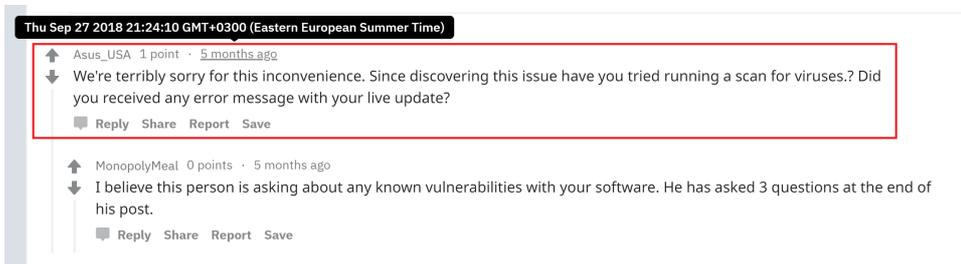

The file uploaded to VT is not one of the malicious compromised updates; we can assume the person who uploaded it actually uploaded the ASUS Live Update itself, as opposed to the update it received from the Internet. Nevertheless, this could suggest that potentially compromised updates were delivered to users as far back as June 2018.

In September 2018, another Reddit user, FabulaBerserko also posted a message about a suspicious ASUS Live update:

Asus\_USA replied to FabulaBerserko with the following message, suggesting he run a scan for viruses:

In his message, the Reddit user FabulaBerserko talks about an update listed as critical, however without a name and with a release date of March 2015. Interestingly, the related attack samples containing the PDB "AsusShellCode.pdb" have a compilation timestamp from 2015 as well, so it is possible that the Reddit user saw the delivery of one such file through ASUS Live Update in September 2018.

## Targets by MAC address

We managed to crack all of the 600+ MAC address hashes and analyzed distribution by manufacturer, using publicly available Ethernet-to-vendor assignment lists. It turns out that the distribution is uneven and certain vendors are a higher priority for the attackers. The chart below shows statistics we collected based on network adapter manufacturers' names:

Some of the MAC addresses included on the target list were rather popular, i.e. 00-50-56-C0-00-08 belongs to the VMWare virtual adapter VMNet8 and is the same for all users of a certain version of the VMware software for Windows. To prevent infection by mistake, the attackers used a secondary MAC address from the real Ethernet card, which would make targeting more precise. However, it tells us that one of the targeted users used VMWare, which is rather common for software engineers (in testing their software).

Another popular MAC was 0C-5B-8F-27-9A-64, which belongs to the MAC address of a virtual Ethernet adapter created by a Huawei USB 3G modem, model E3372h. It seems that all users of this device shared the same MAC address.

## Interaction with ASUS

The day after the ShadowHammer discovery, we created a short report for ASUS and approached the company through our local colleagues in Taiwan, providing all details of what was known about the attack and hoping for cooperation. The following is a timeline of the discovery of this supply-chain attack, together with ASUS interaction and reporting:

- 29-Jan-2019 – initial discovery of the compromised ASUS Live Updater
- 30-Jan-2019 – created preliminary report to be shared with ASUS, briefed Kaspersky Lab colleagues in Taipei
- 31-Jan-2019 – in-person meeting with ASUS, teleconference with researchers; we notified ASUS of the finding and shared hard copy of the preliminary attack report with indicators of compromise and Yara rules. ASUS provided Kaspersky with the latest version of ASUS Live Updater, which was analyzed and found to be uninfected.

- 01-Feb-2019 – ASUS provides an archive of all ASUS Live Updater tools beginning from 2018. None of them were infected, and they were signed with different certificates.
- 14-Feb-2019 – second face-to-face meeting with ASUS to discuss the details of the attack
- 20-Feb-2019 – update conf call with ASUS to provide newly found details about the attack
- 08-Mar-2019 – provided the list of targeted MAC addresses to ASUS, answered other questions related to the attack
- 08-Apr-2019 – provided a comprehensive report on the current attack investigation to ASUS.

We appreciate a quick response from our ASUS colleagues just days before one of the largest holidays in Asia (Lunar New Year). This helped us to confirm that the attack was in a deactivated stage and there was no immediate risk to new infections and gave us more time to collect further artefacts. However, all compromised ASUS binaries had to be properly flagged as containing malware and removed from Kaspersky Lab users' computers.

## Non-ASUS-related cases

In our search for similar malware, we came across other digitally signed binaries from three other vendors in Asia.

One of these vendors is a game development company from Thailand known as **Electronics Extreme Company Limited**. The company has [released](#) digitally signed binaries of a video game called "**Infestation: Survivor Stories**". It is a zombie survival game in which players endure the hardships of a post-apocalyptic, zombie-infested world. According to Wikipedia, "the game was panned by critics and is considered one of the [worst video games of all time](#)". The game servers were taken offline on December 15, 2016."

The history of this videogame itself contains many controversies. According to Wikipedia, it was originally developed under the title of "**The War Z**" and released by **OP Productions** which put it in the [Steam store](#) in December 2012. In April 4, 2013, the game servers were compromised, and the game source code was most probably stolen and [released](#) to the public.

It seems that certain videogame companies picked up this available code and started making their own versions of the game. One such version (md5: de721e2f055f1b203ab561dda4377bab) was digitally signed by **Innovative Extremist Co. LTD.**, a company from Thailand that currently provides web & IT infrastructure services. The game also contains a logo of **Electronics Extreme Company Limited** with a link to their website. The homepage of Innovative Extremist also listed Electronics Extreme as one of their partners.

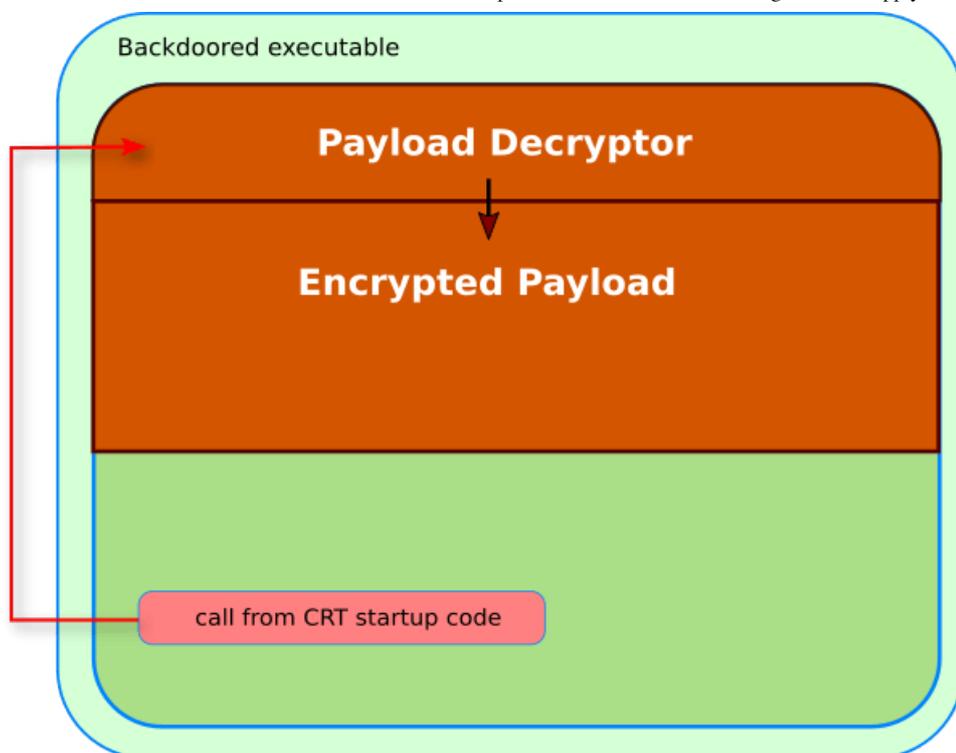

Notably, the certificate from Innovative Extremist that was used to sign *Infestation* is currently revoked. However, the story does not end here. It seems that Electronics Extreme picked up the video game where Innovative Extremist dropped it. And now the game seems to be causing trouble again. We found at least three samples of *Infestation* signed by Electronics Extreme with a certificate that must be revoked again.

We believe that a poorly maintained development environment, leaked source code, as well vulnerable production servers were at the core of the bad luck chasing this videogame. Ironically, this game about infestation brought only trouble and a serious infection to its developers.

Several executable files from the popular FPS videogame *PointBlank* contained a similar malware injection. The game was developed by the South Korean company Zepetto Co, whose digital signature was also abused. Although the certificate was still unrevoked as at early April, Zepetto seems to have stopped using the certificate at the end of February 2019.

While some details about this case were [announced](#) in March 2019 by our colleagues at ESET, we have been working on this in parallel with ESET and uncovered some additional facts.

All these cases involve digitally signed binaries from three vendors based in three different Asian countries. They are signed with different certificates and a unique chain of trust. What is common to these cases is the way the binaries were trojanized.

The code injection happened through modification of commonly used functions such as CRT (C runtime), which is similar to ASUS case. However, the implementation is very different in the case of the videogame companies. In the ASUS case, the attackers only tampered with a compiled ASUS binary from 2015 and injected additional code. In the other cases, the binaries were recent (from the end of 2018). The malicious code was not inserted as a resource, neither did it overwrite the unused zero-filled space inside the programs. Instead, it seems to have been neatly compiled into the program, and in most cases, it starts at the beginning of the code section as if it had been added even before the legitimate code. Even the data with the encrypted payload is stored inside this code section. This indicates that the attackers either had access to the source code of the victim's projects or injected malware on the premises of the breached companies at the time of project compilation.

## Payload from non-ASUS-related cases

The payload included into the compromised videogames is rather simple. First of all, it checks whether the process has administrative privileges.

```
int is_admin()
{
    HANDLE hCurProcess; // eax
    int ret; // esi
    struct _TOKEN_PRIVILEGES NewState; // [esp+4h] [ebp-14h]
    HANDLE TokenHandle; // [esp+14h] [ebp-4h]

    TokenHandle = 0;
    hCurProcess = GetCurrentProcess();
    if ( !OpenProcessToken(hCurProcess, 0x20u, &TokenHandle) )
        return 0;
    NewState.PrivilegeCount = 1;
    LookupPrivilegeValueA(0, "SeDebugPrivilege", (PLUID)NewState.Privileges);
    NewState.Privileges[0].Attributes = 2;
    AdjustTokenPrivileges(TokenHandle, 0, &NewState, 0x10u, 0, 0);
    ret = -(GetLastError() != 0);
    CloseHandle(TokenHandle);
    return ret + 1;
}
```

Next, it checks the registry value at **HKCU\SOFTWARE\Microsoft\Windows\{0753-6681-BD59-8819}**. If the value exists and is non-zero, the payload does not run further. Otherwise, it starts a new thread with a malicious intent.

The file contains a hardcoded miniconfig—an annotated example of the config is provided below.

```
C2 URL: https://nw.infestexe[.]com/version/last.php
Sleep time: 240000
Target Tag: warz
Unwanted processes:
wireshark.exe;perfmon.exe;procmon64.exe;procmon.exe;procexp.exe
;procexp64.exe;netmon.exe
```

Apparently, the backdoor was specifically created for this target, which is confirmed by an internal tag (the previous name of the game is “**The War Z**”).

If any of the unwanted processes is running, or the system language ID is **Simplified Chinese** or **Russian**, the malware does not proceed. It also checks for the presence of a mutex named **Windows-{0753-6681-BD59-8819}**, which is also a sign to stop execution.

After all checks are done, the malware gathers information about the system including:

- Network adapter MAC address
- System username
- System hostname and IP address
- Windows version
- CPU architecture
- Current host FQDN
- Domain name

- **DownUrlFile** – download URL data to file
- **DownRunUrlFile** – download URL data to file and execute it
- **RunUrlBinInMem** – download URL data and run as shellcode
- **UnInstall** – set registry flag to prevent malware start

The UnInstall command sets the registry value

HKCU\SOFTWARE\Microsoft\Windows\{0753-6681-BD59-8819} to 1, which prevents the malware from contacting the C2 again. No files are deleted from the disk, and the files should be discoverable through forensic analysis.

## Similarities between the ASUS attack and the non-ASUS-related cases

Although the ASUS case and the videogame industry cases contain certain differences, they are very similar. Let us briefly mention some of the similarities. For instance, the algorithm used to calculate API function hashes (in trojanized games) resembles the one used in the backdoored ASUS Updater tool.

```

1
2 hash = 0
3 for c in string:
4     hash = hash * 0x21
5     hash = hash + c
return hash

```

```

1
2 hash = 0
3 for c in string:
4     hash = hash * 0x83
5     hash = hash + c
return hash & 0x7FFFFFFF

```

ASUS case

Other cases

### *Pseudocode of API hashing algorithm of ASUS vs. other cases*

Besides that, our behavior engine identified that ASUS and other related samples are some of the only cases where the IPHLPAPI.dll was used from within a shellcode embedded into a PE file.

```

mov     [ebp+var_48], 500049h ; IP
mov     [ebp+var_44], 4C0048h ; HL
mov     [ebp+var_40], 410050h ; PA
mov     [ebp+var_3C], 490050h ; PI

```

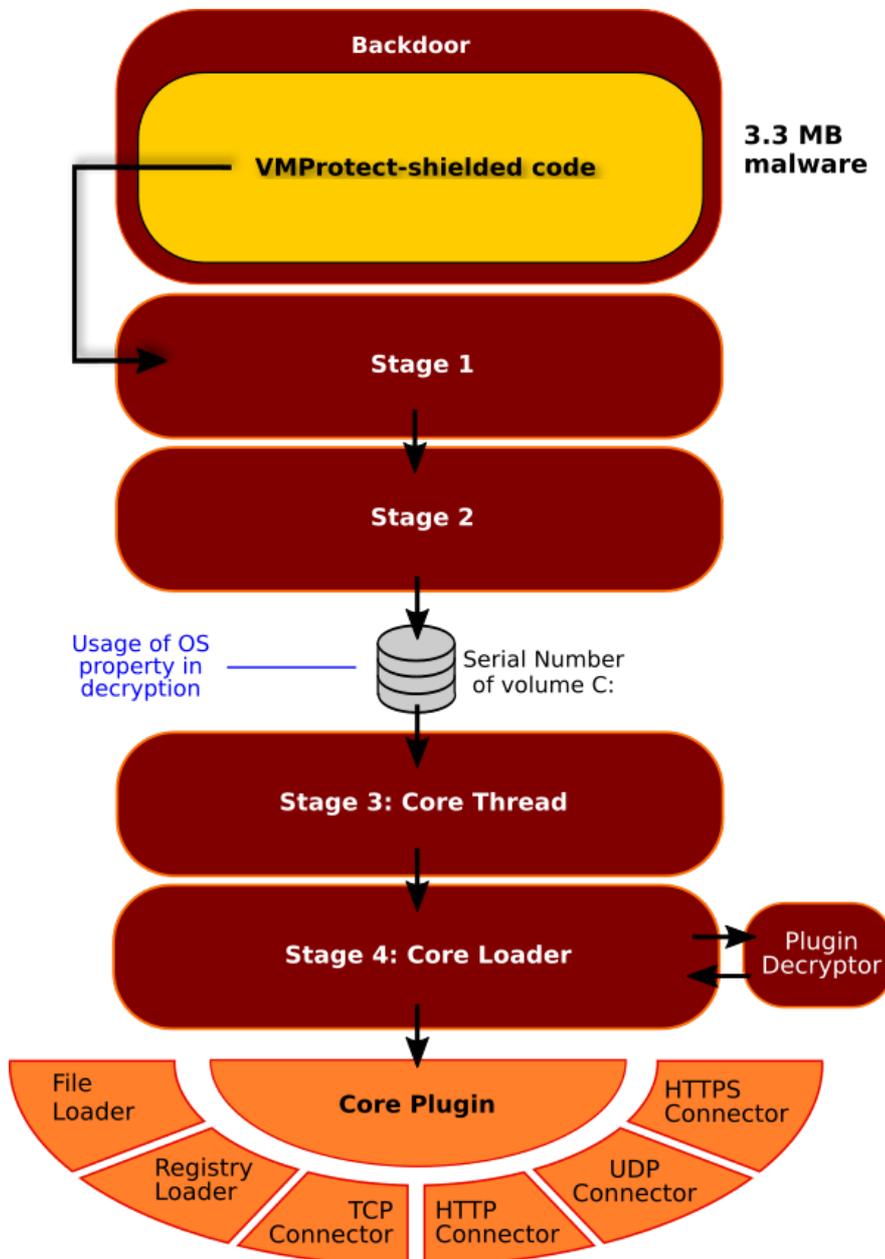

In the case of ASUS, the function GetAdaptersAddresses from the IPHLPAPI.dll was used for calculating the hashes of MAC addresses. In the other cases, the function GetAdaptersInfo from the IPHLPAPI.dll was used to retrieve information about the MAC addresses of the computer to pass to remote C&C servers.

# ShadowPad connection

While investigating this case, we worked with several companies that had been abused in this wave of supply chain attacks. Our joint investigation revealed that the attackers deployed several tools on an attacked network, including a trojanized linker and a powerful backdoor packed with a recent version of VMProtect.

Our analysis of the sophisticated backdoor (md5: 37e100dd8b2ad8b301b130c2bca3f1ea) that was deployed by the attackers on the company's internal network during the breach, revealed that it was an updated version of the ShadowPad backdoor, which [we reported](#) on in 2017.

The ShadowPad backdoor used in these cases has a very high level of complexity, which makes it almost impossible to reverse engineer:

The newly updated version of ShadowPad follows the same principle as before. The backdoor unwraps multiple stages of code before activating a system of plugins responsible for bootstrapping the main malicious functionality. As with ShadowPad, the attackers used at least two stages of C2 servers, where the first stage would provide the backdoor with an encrypted next-stage C2 domain.

The backdoor contains a hardcoded URL for C2 communication, which points to a publicly editable online Google document. Such online documents, which we extracted from several backdoors, were created by the same user under a name of **Tom Giardino (hrsimon59@gmail[.]com)**, probably a reference to the spokesperson from [Valve Corporation](#).

These online documents contained an ASCII block of text marked as an RSA private key during the time of operation. We noticed that inside the private key, normally encoded with base64, there was an invalid character injection (the symbol "\$"):

```
-----begin rsa private key-----  
MIIEpAIBAAKCAQI...  
$hbngpfocidippfmjlkfncndjgneklpglillcjekoblbfllpopmiokjccl$  
...  
-----end rsa private key-----
```

The message between the two "\$" characters in fact contained an encrypted second-stage C2 URL.

We managed to extract the history of changes and collected the following information indicating the time and C2 of ongoing operations in 2018:

```
Jul 31: UDP://103.19.3[.]17:443  
Aug 13: UDP://103.19.3[.]17:443  
Oct 08: UDP://103.19.3[.]17:443  
Oct 09: UDP://103.19.3[.]17:443  
Oct 22: UDP://117.16.142[.]9:443  
Nov 20: HTTPS://23.236.77[.]177:443  
Nov 21: UDP://117.16.142[.]9:443  
Nov 22: UDP://117.16.142[.]9:443  
Nov 23: UDP://117.16.142[.]9:443  
Nov 27: UDP://117.16.142[.]9:443
```

Nov 27: **HTTPS://103.19.3[.]44:443**  
Nov 27: **TCP://103.19.3[.]44:443**  
Nov 27: **UDP://103.19.3[.]44:1194**  
Nov 27: **HTTPS://23.236.77[.]175:443**  
Nov 29: **HTTPS://23.236.77[.]175:443**  
Nov 29: **UDP://103.19.3[.]43:443**  
Nov 30: **HTTPS://23.236.77[.]177:443**

The IP address range 23.236.64.0-23.236.79.255 belongs to the Chinese hosting company **Aoyouhost LLC**, incorporated in Los Angeles, CA.

Another IP address (**117.16.142[.]19**) belongs to a range listed as the Korean Education Network and likely belongs to Konkuk university (konkuk.ac.kr). This IP address range has been [previously reported](#) by Avast as one of those related to the ShadowPad activity linked to the CCleaner incident. It seems that the ShadowPad attackers are still abusing the university's network to host their C2 infrastructure.

The last one, **103.19.3[.]44**, is located in Japan but seems to belong to another Chinese ISP known as "xTom Shanghai Limited". Connected to via the IP address, the server displays an error page from Chinese web management software called **BaoTa** ("宝塔" in Chinese):

安全入口校验失败

103.19.3.44:8888/login

## 请使用正确的入口登录面板

**错误原因:**当前宝塔新安装的已经开启了安全入口登录, 新装机器都会随机一个8位字符的安全入口名称, 亦可以在面板设置处修改, 如您没记录或不记得了, 可以使用以下方式解决

**解决方法:**在SSH终端输入以下一种命令来解决

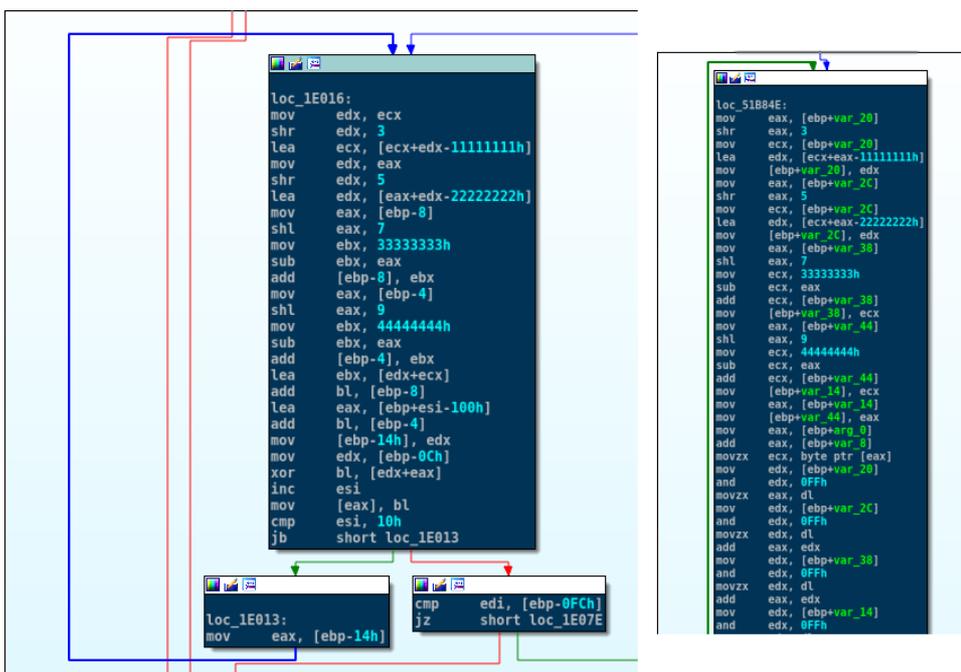

- 1.查看面板入口: /etc/init.d/bt default
- 2.关闭安全入口: rm -f /www/server/panel/data/admin\_path.pl

**注意:**【关闭安全入口】将使您的面板登录地址被直接暴露在互联网上, 非常危险, 请谨慎操作

宝塔Linux面板, [请求帮助](#)

# PlugX connection

While analyzing the malicious payload injected into the signed ASUS Live Updater binaries, we came across a simple custom encryption algorithm used in the malware. We found that ShadowHammer reused algorithms used in multiple malware samples, including many of PlugX. PlugX is a backdoor quite popular among Chinese-speaking hacker groups. It had previously been seen in the Codoso, MenuPass and Hikit attacks. Some of the samples we found (i.e. md5:5d40e86b09e6fe1dedbc87457a086d95) were created as early as 2012 if the compilation timestamp is anything to trust.

Apparently, both pieces of code share the same constants (0x11111111, 0x22222222, 0x33333333, 0x44444444), but also implement identical algorithms to decrypt data, summarized in the python function below.

```
1
2 from ctypes import c_uint32
3 from struct import pack,unpack
4 def decrypt(data):
5     p1 = p2 = p3 = p4 = unpack("&lt;&lt;L", data[0:4])[0];
6     pos = 0
7     decdata = ""
8     while pos &lt; len(data): p1 = c_uint32(p1 + (p1 &gt;&gt; 3)
9         p2 = c_uint32(p2 + (p2 &gt;&gt; 5) - 0x22222222).value
10        p3 = c_uint32(p3 - (p3 &lt;&lt; 7) + 0x33333333).value
11        p4 = c_uint32(p4 - (p4 &lt;&lt; 9) + 0x44444444).value
12        decdata += chr( ( ord(data[pos]) ^ ( ( p1%256 + p2%256 +
13            pos += 1
14        return decdata
```

</pre>

While this does not indicate a strong connection to PlugX creators, the reuse of the algorithm is unusual and may suggest that the ShadowHammer developers had some experience with PlugX source code, and possibly compiled and used PlugX in some other attacks in the past.

## Compromising software developers

All of the analyzed ASUS Live Updater binaries were backdoored using the same executable file patched by an external malicious application, which implemented malware injection on demand. After that, the attackers signed the executable and delivered it to the victims via ASUS update servers, which was detected by Kaspersky Lab products.

However, in the non-ASUS cases, the malware was seamlessly integrated into the code of recently compiled legitimate applications, which suggests that a different technique was used. Our deep search revealed another malware injection mechanism, which comes from a trojanized development environment used by software coders in the organization.

In late 2018, we found a suspicious sample of the link.exe tool uploaded to a public malware scanning service. The tool is part of Microsoft Visual Studio, a popular integrated development environment (IDE) used for creating applications for Microsoft Windows. The same user also uploaded digitally signed compromised executables and some of the backdoors used in the same campaign.

The attack is comprised of an infected Microsoft Incremental Linker, a malicious DLL module that gets loaded through the compromised linker. The malicious DLL then hooks the file open operation and redirects

attempts to open a commonly used C++ runtime library during the process of static linking. The redirect destination is a malicious .lib file, which gets linked with the target software instead of the legitimate library. The code also carefully checks which executable is being linked and applies file redirection only if the name matches the hardcoded target file name.

So, was it a developer from a videogame company that installed the trojanized version of the development software, or did the attackers deploy the Trojan code after compromising the developer's machine? This currently remains unknown. While we could not identify how the attackers managed to replace key files in the integrated development environment, this should serve as a wakeup call to all software developers. If your company produces software, you should ask yourself:

1. Where does my development software come from?
2. Is the delivery process (download) of IDE distributions secure?
3. When did we last check the integrity of our development software?

## Other victims

During the analysis of samples related to the updated ShadowPad arsenal, we discovered one unusual backdoor executable (md5: 092ae9ce61f6575344c424967bd79437). It comes as a DLL installed as a service that indirectly listens to TCP port 80 on the target system and responds to a specific URL schema, registered with Windows HTTP Service API: **http://+/requested.html**. The malware responds to HTTP GET/POST requests using this schema and is not easy to discover, which can help it remain invisible for a long time.

Based on the malware network behavior, we identified three further, previously unknown, victims, a videogame company, a conglomerate holding company and a pharmaceutical company, all based in South Korea, which responded with a confirmation to the malware protocol, indicating compromised servers. We are in the process of notifying the victim companies via our local regional channels. Considering that this type of malware is not widely used and is a custom one, we believe that the same threat actor or a related group are behind these further compromises. This expands the list of previously known usual targets.

## Conclusions

While attacks on supply chain companies are not new, the current incident is a big landmark in the cyberattack landscape. Not only does it show that even reputable vendors may suffer from compromising of digital certificates, but it raises many concerns about the software

development infrastructure of all other software companies. ShadowPad, a powerful threat actor, previously concentrated on hitting one company at a time. Current research revealed at least four companies compromised in a similar manner, with three more suspected to have been breached by the same attacker. How many more companies are compromised out there is not known. What is known is that ShadowPad succeeded in backdooring developer tools and, one way or another, injected malicious code into digitally signed binaries, subverting trust in this powerful defense mechanism.

Does it mean that we should stop trusting digital signatures? No. But we definitely need to investigate all strange or anomalous behavior, even by trusted and signed applications. Software vendors should introduce another line in their software building conveyor that additionally checks their software for potential malware injections even after the code is digitally signed.

At this unprecedented scale of operations, it is still a mystery why attackers reduced the impact by limiting payload execution to 600+ victims in the case of ASUS. We are also unsure who the ultimate victims were or where the attackers had collected the victims MAC addresses from. If you believe you are one of the victims, we recommend checking your MAC address using this [free tool](#) or [online check website](#). And if you discover that you have been targeted by this operation, please email us at [shadowhammer@kaspersky.com](mailto:shadowhammer@kaspersky.com).

We will keep tracking the ShadowPad activities and inform you about new findings!

## Indicators of compromise

### C2 servers:
